Abstract

In this experiment, the extrusion of high-density polyethylene and cycloac was explored using a single screw extruder with a long (125mm) and small diameter (3.125mm) die. The die & extruder characteristics, which can be defined by the relationship between the wall shear rate and shear stress, was created to describe the apparatus. For polyethylene, the extruder was discovered to have the expected non-Newtonian behavior. While, the cycloac didn't show the expected trend. The viscosity of polyethylene was shown to decrease with increase shear rate. This was due to the non-Newtonian behavior of the fluid. A phenomenon known as shear thinning is the cause of this trend. In addition, the mass flow rate was discovered to increase linearly with increasing screw speed, which was varied from 5-30 rpm. The extrudate swell was also measured against shear rate. The data showed that as shear rate increased the extrudate swell also increased. Lastly, the differential scanning calorimetry (DSC) was used to determine the crystallinity of polyethylene and cycloac. The DSC confirmed the semi-crystalline and amorphous nature of polyethylene and cycloac respectively. The DSC resulted in a 27.7% and 29.2% crystallized polyethylene for the 5 and 10 RPM respectively with a 170 °C melting temperature and a recrystallization temperature of 25 °C. Reheating resulting in a crystallinity increase to 29.9% and 30.6% respectively, this, corresponds to a greater organization of polymer chains after the polymer was allowed to recrystallize.

Introduction

Polymer extrusion is an important industrial process, used when a continuous production of uniform profile is required. A myriad of products are gotten from polymer extrusion. These products are derived by melting thermoplastics and extruding it through a die. The shape of the die determines the shape of the polymer product.

Thermoplastics are commonly used raw materials for polymer extrusion, which include polyethylene, polypropylene, polystyrene, PVC, nylon and polycarbonate. These thermoplastic materials are used in polymer extrusion because they become soft and melt when heated and turn solid when cooled. In return, these materials can form a plethora of products varying from liners and foil to tubing, wiring, and even plastic bags. Sheet extrusion, tubing extrusion, and blown film extrusion are specific types of polymer extrusion processes that are optimized to produce these products [1].

Figure 1: Chemical structure of ABS.

[2]

Figure 2: Chemical structure of HDPE

[3]

In this experiment, a single screw extruder was used to extrude Cycolac (ABS) and Marlex 5502BN (HDPE). The research goals for this experiment were to characterize a small circular die while extruding ABS and HDPE through it.

Background

The polymers used in the lab were Marlex brand high-density polyethylene (HDPE) and Cycolac brand acrylonitrile butadiene styrene (ABS). HDPE is a very durable material with excellent stiffness and is widely used from plastic water bottles to pipeline. This polymer has a density of 0.964 g/cm^3 and a melting temperature between 90°C - 140°C [6]. ABS is resistant to much higher temperatures and gets mechanically stronger over time with high impact strength and stiffness. This polymer has a melting temperature between 190°C - 250°C [7]. When heated above the melting point the polymer turns to a liquid which then allows a screw to push it through a die. Once exited the die it is cooled and the polymer chains reform resulting in what is called the extrudate. HDPE is characterised to be a semi-crystalline polymer, while ABS on the other hand, is amorphous.

Shear viscosity of a fluid is the resistance to deformation from stress or resistance to flow [4]. For a Newtonian fluid, shear viscosity is defined as the shear stress divided by the shear rate as described in (1).

$$\mu = (\tau/\dot{\gamma}) \quad (1)$$

where η is the viscosity of the fluid, τ is the shear stress on the fluid, and $\dot{\gamma}$ is the shear rate applied to the fluid [4]. A unique property about polymeric liquids is the more shear rate is

increased the more it deviates from the ideal shear viscosity. For this reason, some polymers must be modelled as non-Newtonian fluids [4]. This introduces a new variable n which shows the deviation of the fluid from Newtonian behaviour. Therefore, when $n=1$, the fluid is Newtonian, when $n>1$ the fluid has dilatant behavior, and when $n<1$, in the case of polymers, the fluid has pseudoplastic behaviour. Dilatant behavior can be characterized by a decrease in viscosity while the shear rate is increasing. Pseudoplastic behaviour can be characterized by an increase in viscosity while the shear rate is increasing. The shear viscosity and shear stress of a non-Newtonian fluid can be described with (2) and (3).[5].

$$\mu = m\dot{\gamma}^{n-1} \quad (2)$$

$$\tau = m\dot{\gamma}^n \quad (3)$$

For a circular die, as used in the experiment, there are characteristic equations that can be used to calculate shear rate and the shear stress. The relationship between shear rate to radius of pressure drop across the die, ΔP , the length of die, L , and the diameter of the die, D by (4). The relationship of the shear rate to the volumetric flow rate, Q , and the radius of the die, R , by (5).[5].

$$\tau = D\Delta P/4L \quad (4)$$

$$\dot{\gamma} = 4Q/\pi R^3 \quad (5)$$

These can then be plugged into (1) and the viscosity of the polymeric melt can be calculated.

This, however, is assuming the polymer acts as a Newtonian fluid which it does not. For this reason, the Rabinowitsch correction is needed. In the Rabinowitsch correction constant pressure drop is assumed through the die. [5] .Here there is the apparent shear rate, which is the

shear rate of a Newtonian fluid, or (5), there is also a corrected shear stress given by (6), which relates apparent shear rate to the unit less correlation b , given by equation (7).

$$\gamma_w = (3+4/b) * \gamma_A \quad (6)$$

$$b = d(\log \gamma_A) / d(\log \tau) \quad (7)$$

This then calls for a new viscosity of the non-newtonian fluid relating the corrected shear stress to the shear rate given by (8).

$$\mu = \tau / \gamma_w \quad (8)$$

With polymer extrusion, there is something known as extrudate swell where after the extrudate exits the end of the die, its diameter increases to bigger than that of the die. This results from residual stress in the polymer as it travels through the extruder. The difference in temperature between the hot polymer exiting the polymer and the outside temperature can affect how much it swells. The extrudate swell related to the extrudate cross sectional area divided by the die cross sectional area is given by (9) [4].

$$\text{Extrudate Swell} = \frac{\text{Extrudate Cross Sectional Area}}{\text{Die Cross Sectional Area}}$$

(9)

Experimental Procedure

Before the lab session, two trays with polymer were placed in the oven to remove moisture. Zone temperatures were specified in the TRF submitted for every session. For HDPE the benchmark temperature profile was 70°C, 90°C, 130°C, 170°C, 170°C for zones 1-3,5,6

respectively. We changed temperatures for zones 2,3,5,6, but zone 1 remained at 70°C as it is below melting point of HDPE and solid polymer in zone 1 pushes on the liquid further in the extruder. Similarly, while performing experiments on cycolac (ABS), we consistently kept zone 1 at 180°C. The extruder was cleaned by the TAs prior to loading polymer in the hopper.

Heated polymer was transferred from the tray into the hopper. Safety gloves were used to avoid skin burns. After extruder zones reached their respective temperatures, the machine was turned on and extruder speed was set to the desired value. We obtained samples at 5, 7, 10, 15, 20, 25, 30 RPM. Conveyor belt speed was set to match the speed of the extrudate by adjusting the dial and visual inspection in order to avoid thinning.

Three samples were taken for each RPM-temperature profile set. Samples were weighed on a scale and their mass was divided by time it took to produce samples to obtain mass flow rate. The diameter of the samples was measured via calipers and divided by the diameter of the circular die to obtain the swell ratio.

To perform DSC crystallinity testing, samples had to be made by punching out 8-12 mg of the desired extrudate using a leather hole puncher while using gloves. The samples were then placed into an aluminum pan with a lid crimped over it. The sample was then placed in the machine in its respective spot and then the machine was turned on. To ensure the sample completely melted in the DSC trials, the machine got to about 10 degrees below the selected temperature, so temperatures about 40-50 degrees above melting point. Taking this into account, for HDPE the temperature was set to start at 20°C go up to 170°C at 20°C/min, then go from 170°C to 25°C at 10°C/min, and finally go from 25°C back up to 170°C at 20°C/min. For cycolac the temperature was set to start at 20°C go up to 315°C at 20°C/min, then it goes down to 25°C at 10°C/min, and finally back up to 315°C at 20°C/min. The DSC testing was performed twice in

order to let the polymer recrystallize on its own. This was performed in order to see the true crystallinity of the polymer due to the fact that when the polymer is first extruded it may cool too quickly thus preventing it from crystallizing properly.

Results and Discussion

Crystallinity

The crystallinity of polyethylene marlex 5502 and cyclac(ABS) was investigated. From the literature, it has been stated that polyethylene is a semi-crystalline polymer with a possible range of 25%-85% crystallinity (citation). While, Cyclac has been stated to be an amorphous polymer (citation). As can be seen on table 1, the polyethylene shows that it is a semi-crystalline polymer. In addition, as can be seen the second heating crystallinity is higher than the first, showing the real crystallinity of polymer. Lastly, as can be seen the increase in RPM and in addition torque doesn't affect the crystallinity. In table 1, cyclac can be seen to have an extremely low crystallinity. Therefore, showcasing its amorphous properties.

Table 1: Percent crystallinity of polymers at different temperature profiles and RPMs

| Polymer tested | Temperature profile | RPM | First heating crystallinity | Second heating crystallinity |
|----------------|---------------------|-----|-----------------------------|------------------------------|
| Polyethylene | 70/120/150/180/200 | 5 | 27.7% | 29.5% |
| Polyethylene | 70/120/150/180/200 | 10 | 29.2% | 30.6% |
| Cyclonac | 180/200/220/250/260 | 5 | 3.1% | 3.2% |

Shear Stress vs. Shear Rate

The die characteristics can be analyzed by a shear stress and shear rate graph. In figure 3, it can be seen that as the shear rate increases the shear stress also increases. As can be seen from figure 3, for polyethylene the relationship of shear stress to shear rate isn't linear. This can be attributed to its non-Newtonian characteristics. This figure indicates that the polyethylene is undergoing “shear thinning” due to its non-Newtonian characteristics. From the figure 3, it can be seen that at increasing temperature the effect of increase shear rate doesn't increase the level of shear stress. This is intuitive because at increase die temperature the fluid will be more easily

Figure 3: Shear rate vs Shear Stress graph of Polyethylene with zone temperatures :Z1: 70°C, Z2: 100°C, Z3: 140°C, Z5: 180°C and only zone 6 was varied.

extruded at each shear rate thus inducing less stress. However, figure 4 doesn't show the same for cyclac. This is primarily due to the lack of sufficient data points collected during the course of the experiment.

Figure 4: Shear rate vs Shear Stress graph of cyclac with temperature profile Z1: 180°C, Z2: 210°C, Z3: 230°C, Z5: 260°C, with only zone 6 being varied.

Viscosity vs. Shear Rate

For the small circular die the effect of viscosity with increasing shear rate was identified. In figure 5, you can see that as shear rate increases, viscosity decreases for all temperature profiles of polyethylene. This doesn't only align with the expected trend from the literature [8]. This also aligns with the trend from the theory that indicates that a non-Newtonian fluid viscosity decreases with increasing shear rate. This is an effect of "shear thinning" which is to be expected since polyethylene melt is a pseudo plastic fluid.

Cyclac, shown in figure 6, however has conflicting trends with one experimental trial having a positive slope while the other displaying the opposite. This is probably the result of a small experimental screw speed range when extruding the cyclac which prevented the establishment of a concrete trend. With cyclac only trials between 10-20 rpm were experimented with and if this range were widened, then the shear thinning would also be apparent with cyclac.

Figure 5: Viscosity vs Shear rate graph of Polyethylene for the following temperature profile: Z1: 70°C, Z2: 100°C, Z3: 140°C, Z5: 180°C, & zone 6 varied

Figure 6: Viscosity vs Shear rate of cyclac for the following temperature profiles Z1: 180oC, Z2: 210oC, Z3: 230oC, Z5: 260oC and Z6 being varied

Mass flowrate vs Screw Speed

As can be seen in figure 7, the mass flowrate increases with increasing screw. This is as a result of more material being able to be pushed out due to the increased screw speed. In addition, even though there may be some slight overlap; it can be seen that at increasing temperatures for the same screw speeds there are higher mass flow rates. This is as a result of decreased viscosity that is expected to decrease, meaning more material can be pushed forward with a single screw turn. The results shown in figure 7, align with the results gotten in the literature; that with increasing screw speed the mass flowrate should increase [8].

Figure 7: Mass flowrate vs Screw speed for the following temperature profiles : for the following temperature profile: Z1: 70°C, Z2: 100°C, Z3: 140°C, Z5: 180°C, & zone 6 varied

Extrudate swell

The extrudate swell was measured to determine the ratio between the extrudate exiting the apparatus and the diameter of the long die, 3.125 mm. As shown on figure 8, the extrudate ratio showed a trend of increasing ratio with increasing shear rate. This can be result of the shear thinning effect as the shear rate increasing, the viscosity decreases, allowing for the polymer to expand more.

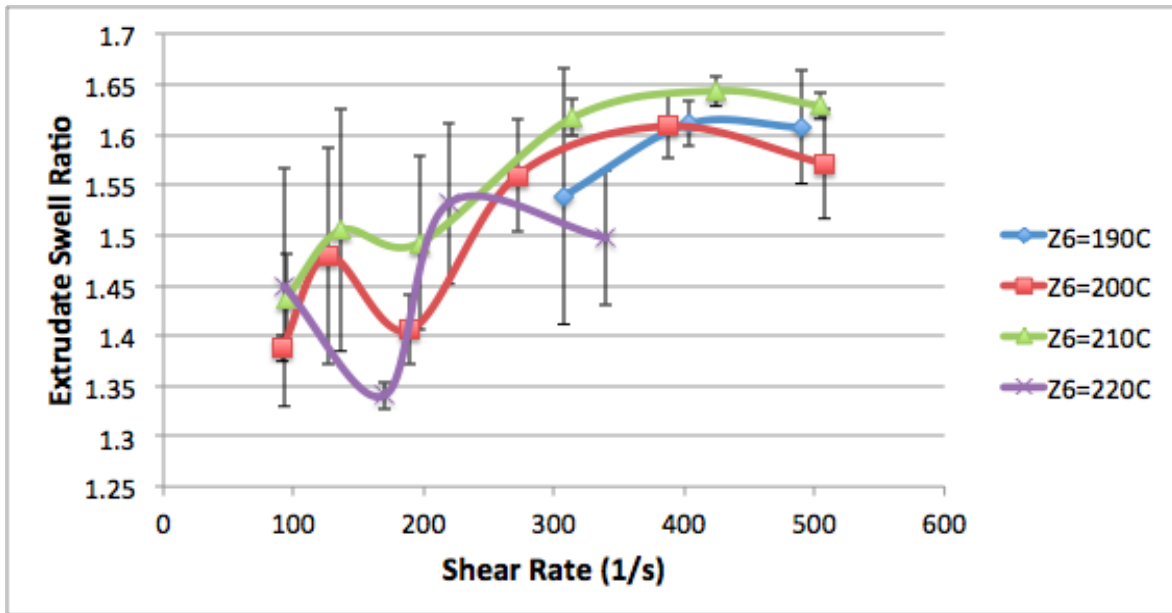

Figure 8: Extrudate swell ratio vs Shear rate for polyethylene for the following temperature profile: Z1: 70 °C, Z2: 100 °C, Z3: 140 °C, Z5: 180 °C, & zone 6 varied

Conclusion and Recommendations

The high-density polyethylene marlex 5502 BN and the cyclac resin were successfully extruded from the Haake Rheo Drive using seven increasing extruder heating zone profiles under six increasing screw speed values to evaluate fluid flow and material properties of the processed polymer. The polymers resins used were both analyzed after extrusion to discover their crystallinity with the aid of a differential scanning calorimetry (DSC). The DSC confirmed the semi-crystalline and amorphous nature of polyethylene and cyclac respectively. The DSC resulted in a 27.7% and 29.2% crystallized polyethylene for the 5 and 10 RPM respectively with a 170 °C melting temperature and a recrystallization temperature of 25 °C. Reheating resulting in a crystallinity increase to 29.9% and 30.6% respectively, this, corresponds to a greater organization of polymer chains after the polymer was allowed to recrystallize. The mass flow and thermodynamic data were gathered during the extrusion of samples to generate a shear rate

vs shear stress profile. From the figure 3, it can be seen that at increasing temperature the effect of increase shear rate doesn't increase the level of shear stress. For polyethylene, the extruder was shown to have the expected non-Newtonian behavior. While, the cyclac didn't show the expected trend. The viscosity of polyethylene was shown to decrease with increase shear rate. This was due to the non-Newtonian behavior of the fluid. A phenomenon known as shear thinning is the cause of this trend. In addition, the mass flow rate was discovered to increase linearly with increasing screw speed, which was varied from 5-30 rpm. The extrudate swell was also measured against shear rate. The data showed that as shear rate increased the extrudate swell also increased.

I would recommend to future groups to focus their research primarily on cyclac. During this round, the data gotten coincided with what was expected for polyethylene and in addition aligned with what other groups got. However, without sufficient amount of data to be able to make decent graphs, no useful information could be gotten for to characterize the single screw extruder for cyclac.

Appendix

A. Sample Calculations

1. Extrudate Swell

$$\text{Extrudate swell} = \frac{\text{Diameter of Polymer}}{\text{Diameter of die}}$$

2. Shear Stress

For a capillary die:

$$\tau_w = \frac{R}{2} \left(\frac{\Delta P}{L} \right)$$

Example: R = 0.0022m, L = 0.03m, ΔP = 260psig

$$\tau_w = \frac{0.0022}{2} * 260 \text{psig} * \frac{6894.76 \text{ Pa}}{\text{psig}} * \frac{1}{0.03} = 65730 \text{ Pa}$$

3. Apparent Shear Rate

For a capillary die:

$$\dot{\gamma}_a = \frac{4Q}{\pi R^3}$$

Example: $Q = 1.33 \times 10^{-7} \text{ m}^3/\text{s}$, $R = 0.0022 \text{ m}$

$$\gamma_a = \frac{4 * 1.33 \times 10^{-7}}{3.14 * 0.0022^3} = 15.9 \text{ s}^{-1}$$

4. Non-Newtonian Shear Rate

For a capillary die:

$$\gamma_w = \frac{3n+1}{4n} \left(\frac{4Q}{\pi R^3} \right) = \frac{3n+1}{4n} \dot{\gamma}_a$$

Example: $n = 0.7$, $\gamma_a = 16 \text{ s}^{-1}$

$$\gamma_w = \left(\frac{3(0.7) + 1}{4(0.7)} \right) (16) = 17.714 \text{ s}^{-1}$$

5. Viscosity

$$\eta = \frac{\tau_w}{\dot{\gamma}_w}$$

Example: $\tau_w = 65730 \text{ Pa}$, $\gamma_w = 17.7 \text{ s}^{-1}$

$$\eta = \left(\frac{65730}{17.7} \right) = 3700 \text{ Pa} * \text{s}$$

Safety Assessment Form for Experiments (SAFE)

Chemical Engineering Laboratory
Department of Chemical Engineering
University of Massachusetts Amherst

| | | | |
|--|---|-------------------------------------|---|
| Process Name Polymer Extrusion | | Process Location Gsm 61 | Hazard Level ** 1 |
| Written by Shuaib, Balogun | | Group Code * D2 | Date 01/29/18 |
| Required Non-Standard PPE: | | | |
| Hard Hat No | Gloves (specify type) heat protecting gloves when handling over | Face Shield No | Other PPE |
| Description of Procedure | Potential Hazards | Recommended Safety Procedure | Required Personal Protective Equipment |
| Extrusion | Hot Polymer | Handle safely | PPE, thermal |
| Extrusion | Moving parts | Keep hands & feet away | PPE |
| | | | |

Safety Awareness

Nearest Fire Extinguisher:

Nearest Eye Wash:

Nearest Safety Shower:

Nearest Emergency Exit:

Nearest First-Aid Kit:

Nearest Telephone (Landline):

Emergency Shutdown Procedure:

By Entrance to room 61
by heat exchanger in 61
by entrance to room 61
by entrance to room 61
by entrance to room 61
by entrance to room 61
press big red button

Left station in safe state (clean and orderly; chemicals and samples properly labeled or disposed)

| Date | Time | TA initials |
|----------|-------|-------------|
| 01/30/18 | 04:30 | Y.J. |
| 02/01/18 | 03:52 | Y.J. |
| 02/06/18 | 04:08 | Y.J. |
| 02/13/18 | 04:14 | Y.J. |

* Group letter and number

** For the purpose of this course, highest NFPA rating of chemicals used.
